Abstract

The aim of this study was to reveal the clinical features of anterior urethral recurrence in patients with superficial bladder cancer, and to determine the appropriate treatment. Three hundred and three patients with superficial bladder cancer, who were newly diagnosed and initially treated conservatively in our hospital between 1965 and 1990, were followed for at least 5 years and their clinical outcomes were analyzed. Clinical factors, including anterior urethral recurrence, were evaluated statistically regarding tumor progression. Eight patients (2.6%) had anterior urethral recurrence following superficial bladder cancer. Twenty-four patients (7.9%) had tumor progression and 149 (49.2%) had tumor recurrence. In a multivariate analysis using a logistic model, anterior urethral recurrence was the most important factor, followed by histological grade. Four of 5 patients who were treated for anterior urethral recurrent tumors by transurethral resection showed progression and died of the cancer within one year. Two of the remaining three patients who underwent radical cysto-urethrectomy at the time of anterior urethral recurrence survived. Anterior urethral recurrence following superficial bladder cancer is a predictor for rapid subsequent malignant progression. Once there is anterior urethral recurrence, radical intensive therapy, including radical cysto-urethrectomy, should be carried out immediately.

The aim of this study was to reveal the clinical features of anterior urethral recurrence in patients with superficial bladder cancer, and to determine the appropriate treatment. Three hundred and three patients with superficial bladder cancer, who were newly diagnosed and initially treated conservatively in our hospital between 1965 and 1990, were followed for at least 5 years and their clinical outcomes were analyzed. Clinical factors, including anterior urethral recurrence, were evaluated statistically regarding tumor progression. Eight patients (2.6%) had anterior urethral recurrence following superficial bladder cancer. Twenty-four patients (7.9%) had tumor progression and 149 (49.2%) had tumor recurrence. In a multivariate analysis using a logistic model, anterior urethral recurrence was the most important factor, followed by histological grade. Four of 5 patients who were treated for anterior urethral recurrent tumors by transurethral resection showed progression and died of the cancer within one year. Two of the remaining three patients who underwent radical cysto-urethrectomy at the time of anterior urethral recurrence survived. Anterior urethral recurrence following superficial bladder cancer is a predictor for rapid subsequent malignant progression. Once there is anterior urethral recurrence, radical intensive therapy, including radical cysto-urethrectomy, should be carried out immediately.

Key words: superficial bladder cancer, anterior urethral recurrence, prognosis, predictor

Clinical problems associated with superficial bladder cancer are local recurrence and progression to the advanced stage. Superficial bladder cancer itself is not a life-threatening disorder, provided it remains within the bladder mucosa. Once this type of cancer progresses to local muscle invasion or metastasis, anticancer management strategies such as radical surgery, systemic chemotherapy, or radiation therapy may have little effect, and the prognosis may be poor. Therefore, prediction of progression is a major issue in the clinical management of superficial bladder cancer. While numerous markers used to analyze the prognostic factors of superficial bladder cancer have been reported [1–6], anterior urethral recurrence of superficial bladder cancer has not been discussed as one of these prognostic factors, thus prompting our evaluation.

Materials and Methods

We statistically analyzed factors affecting progression in patients with superficial bladder cancer. From 1965 to 1990, 384 patients with superficial bladder transitional...
carcinoma (without concomitant carcinoma in situ; CIS) were newly diagnosed in our hospital. Among these 303, those who received conservative transurethral resection (TUR) and were followed for at least 5 years or until death, were evaluated in this study. Eighty-one patients were excluded from the analysis, since they underwent incomplete initial treatment or dropped out of follow-up treatment. In this study, malignant progression was defined as a local invasion over the muscle layer, lymph node metastasis, or distant metastasis. There were 257 male and 46 female patients whose age ranged from 19 to 88; the mean age was 61.4. The mean period of follow-up for patients was 84.0 months, ranging from 30 to 330 months. The patients were followed as described; cystoscopy was performed every 3 months for 2 years after TUR, then every 4 months from 2 to 3 years, every 6 months from 3 to 5 years, and annually after 5 years. Urine cytology was examined at the time of cystoscopy. Intravenous pyelography, pelvic computed tomography (CT), and chest radiography were performed annually. For the statistical analysis of the factors at the time of initial treatment, uni-variate and multi-variate analyses by Cox’s proportional Hazards model were performed. The factors and the categories of statistical analysis were age, sex, clinical symptoms, number of tumors, tumor size, tumor shape, tumor involvement of the bladder neck, stage based on UICC 1997, and grade (highest grade in cases involving multiple grades). In 149 patients with tumor recurrence, factors related to tumor progression were analyzed using a logistic model. A $P$ value of less than 0.05 was considered statistically significant in the uni-variate analysis.

The clinical outcomes of patients with anterior urethral recurrence of superficial bladder cancer were also analyzed. A total of 8 patients suffered from anterior urethral recurrence during this period. In this study, anterior urethral recurrence was defined as follows: tumor recurrence at the anterior urethra excluding the prostatic urethra and bladder neck in males, and tumor recurrence at the urethra excluding the bladder neck in females.

**Results**

During the follow up period, there were recurrences in 149 patients and among these, there was progression in 24 patients. These recurrent cases were analyzed according to the factors and categories shown in Table 1. The factors were evaluated in terms of their impact on

malignant progression. In the uni-variate analysis, ante-
rior urethral recurrence, and tumor shape, grade, and
stage all had a statistically significant correlation with
progression. In the multivariate analysis using a logistic
model, anterior urethral recurrence was the most im-
portant predictor of progression, followed by histologi-
cal grade (Table 2). There was anterior urethral recurrence in
8 patients at 14 to 148 months (median: 47.5) after the
initial diagnosis, with no obvious sub-mucosal invasion
apparent upon pre-operational examinations such as ureth-
roscopy and CT. All of these patients had concomitant
bladder recurrence. In 6 of the 8 patients, pre-operational
examination revealed concomitant bladder cancer without
and 2 cases with muscle infiltration. Five of the 6 patients
with concomitant bladder cancer and without muscle
infiltration were treated by transurethral resection without
additional chemo- or radiation therapy; the latter 2 pa-
tients with muscle infiltration underwent radical cysto-
urethrectomy. The remaining patient underwent cysto-
urethrectomy for multiple tumor recurrence, although no
obvious sub-mucosal invasion had been observed before
surgery. Histo-pathological findings in the urethrectomy
specimens of these 3 patients revealed micro-invasion into
the prostate and/or into the deep muscle wall. After addi-
tional adjuvant systemic chemotherapy was performed
on these 3 patients, 2 patients showed no evidence of
recurrence, and one died of the cancer 2 months after the
surgery. Malignant progression (3 patients with local
invasive recurrence and 1 patient with a distant meta-
tasis) was revealed during the follow-up treatment period
as described above. Thus, Malignant progression was
observed in 4 of the 5 patients who were treated conserva-
tively, 9 to 37 months after the transurethral manage-
ment. These 4 patients received intensive therapy, includ-
ing radical cysto-urethrectomy and systemic chemother-
apy. However, each patient had a poor prognosis and
died within 1 year. Transurethral management succeeded
in controlling the disease in only one patient with anterior
urethral recurrence. The summaries and clinical courses of
these 8 cases are shown in Table 3.

On the other hand, among the five cases involving
progression without urethral recurrence, had lymph node
metastasis with local progression, two had distant meta-
tasis without local progression, and one had distant
metastasis with lymph node metastasis and local progres-
sion.

**Discussion**

Numerous factors that are prognostic of superficial
bladder cancer have been reported for use as markers.
However, there is no definite marker for determining the
treatment of superficial bladder cancer. Recent advances
in molecular biological techniques have revealed many
factors such as oncogenes and onco-suppressor genes that
may affect the clinical course of superficial bladder cancer.
Intensive studies have shown that among the several
identified prognostic markers, the status of suppressor
gene p53 mutation, the Ki-67 labeling index, and EGFr
are very useful. Detection of malignant phenotypes,
especially those related to local invasion and metastasis,
are the major subjects of cancer research. However, the
suggested impact of these factors (e.g., prognostic
molecular markers, tumor number, tumor size, tumor
grade, and CIS varies among reports [1–6]. Moreover,
there have been no definitive clinical evaluations to date,
and it remains difficult to predict global clinical courses
according to minute molecular biological changes. In
addition, the standard treatment strategy for patients with
concomitant CIS differs from that for patients without

Radical, radical cysto-urethrectomy.

Our results suggest that anterior urethral recurrence following superficial bladder cancer is a significant predictor of malignant progression. Although some clinical reports [7-12] have described urethral recurrence after cystectomy for advanced bladder cancer, as well as the occurrence of primary anterior urethral cancer, there have been few clinical studies on urethral recurrence following superficial bladder cancer. Eckert et al. [12] reported the clinical features of urethral tumor involvement in 910 male patients with bladder cancer at all stages; although the patient number is large, the criteria for urethral recurrence included both the anterior and posterior urethra, without distinguishing between the 2 types of tumor. Our retrospective study is one of the few that deal specifically with the clinical significance of anterior urethral recurrence following superficial bladder cancer.

It has been a long-term matter of debate whether such metachronous tumors represent the unrecognized direct extension of bladder cancer, the seeding of cancer cells from the bladder, metastasis, or a second manifestation of a multicentric defect of the transitional cell mucosa that caused the original bladder cancer. Freeman et al. [9] supported the latter theory in cases of post-radical cystectomy, since urethral tumors occur variably throughout the length of the anterior urethra as skip lesions and in the absence of a positive surgical margin. The results of that study did not support the theory of mechanical implantation, since urethral tumors tend not to occur in areas of stricture, which presumably represent sites of mucosal trauma and thus the most fertile ground for seeding. If this speculation is true across the board, conservative treatment may be feasible, provided the tumor is superficial. However, such speculation is based on the results of urethral recurrence after radical cystectomy. It is important to consider the circumstance in which continuous urinary flow from upstream lesions may contain cancer cells that are then transported to the urethra. These conditions differ radically from those of a post-radical cystectomy, in which mechanical implantation from a superficial bladder cancer seems primary. Mechanical implantation may lead to more invasive tumors of the anterior urethra than would be expected among second-manifestation tumors due to multicentric defects of the transitional cell mucosa; this would be the case because the injured urethral mucosa into which the cancer cells are implanted is thin, as is the muscle wall, and is adjacent to cavernous tissue with abundant blood flow. Cancer cells may easily migrate into the blood stream and cause distant metastasis in such circumstances. In fact, histopathological examination of our patients with urethral recurrence who had undergone radical cysto-urethrectomy immediately revealed micro-invasion to deep sites, and 4 of the 5 patients who were treated conservatively for anterior urethral recurrences had poor prognoses. These findings indicate the potent ability of cancer cells to migrate and eventually form local invasions and distant metastases at the time of anterior urethral recurrence. Since urethral recurrence of superficial bladder cancer can be regarded as a sign of the high malignancy of cancer cells, immediate radical and systematic therapy, including cysto-urethrectomy, chemotherapy, or radiation therapy, should be performed as soon as recurrence is diagnosed. To prevent tumor seeding, the urethral mucosa should be

http://escholarship.lib.okayama-u.ac.jp/amo/vol57/iss6/5

4
protected during any transurethral maneuver. Although this was not a randomized prospective study, the following conclusions can be drawn from the present results: 1] anterior urethral recurrence of superficial bladder cancer could be a significant prognostic factor; 2] immediate radical systematic intensive therapy should be performed in such cases; 3] precise urethrosopic examination should also be performed during the routine follow-up treatment for superficial bladder cancer.
