ABSTRACT

The details of photoluminescence and excitation spectra of powder phosphors were obtained at various temperatures between 6 and 300 K. At 300 K, two emission bands originating from the $^2T_2g(5d)$ --$^2F_{7/2}, ^2F_{5/2}(4f)$ transitions are observed at 480 and 535 nm for SrS:Ce$^{3+}$ and at 470 and 527 nm for SrSe:Ce$^{3+}$, respectively. In the excitation spectra, bands corresponding to the $^2F_{sn}(4f)$ --$^2T_2g(5d)$ transition are observed at 433 (SrS:Ce$^{3+}$) and 430 nm (SrSe:Ce$^{3+}$), and plateaus due to the fundamental absorption of the host crystals in higher energy region. The vibrational structures on the emission and excitation bands are analyzed by the use of energy matrices in order to determine the coupling constant of spin-orbit interaction $\lambda$ and the crystal field parameters $V_4, V_{4s}$ for the 4f orbit.

Alkaline earth chalcogenides are known as excellent host crystals of phosphors. In particular, the SrS:Ce$^{3+}$ phosphor has been investigated in relation to its availability for cathodo- (1) and electroluminescence devices (2). Its photoluminescence (PL) and excitation spectra, however, are not yet analyzed in detail from the standpoint of the energy terms. The 4f orbit of a Ce$^{3+}$ ion incorporated in a crystal is electrically screened by the 5s$^2$5p$^6$ electrons, whereas the 5d orbit splits into the eg and t$_2g$ orbits under the strong influence of an O$_6$ crystal field. The $^2F_{5/2}$ and $^2F_{7/2}$ states originating from the 4f configuration in the LS approximation slightly split into respective substates $^2F_{6, 7}$, $^2F_{6, 5}$, and $^2F_{6, 6}$ in the crystal field. The $^2T_{2g}$ state splits into $^2I_g$ and $^2I_g$ substates on account of the spin-orbit interaction. One can observe, in general, two emission bands corresponding to the transitions from the lowest excited state $^2T_{2g}$ to the $^2F_{5/2}$ and $^2F_{7/2}$ states (1-5).

We have already investigated MgS, CaS, and CaSe phosphors activated with Ce$^{3+}$ ions (4, 5). In the present paper, SrS:Ce$^{3+}$ and SrSe:Ce$^{3+}$ phosphors are studied and the results are compared with those obtained in previous investigations, in order to elucidate the effect of host ingredients on the luminescence of Ce$^{3+}$ ions.

Experimental

Preparations.—The host material, SrS, was prepared by sulfurating the purified strontium carbonate at 1000°C for 50 min in a stream of H$_2$S. On the other hand, SrSe was prepared by reducing the purified strontium selenide selenate at 600°C for 70 min in a stream of H$_2$. The product, SrSe, was reheated at 1080°C for 30 min in N$_2$ in order to stabilize it chemically. The details are described in a previous paper (6).

We prepared the SrS:Ce$^{3+}$ phosphor by firing the mixture of the strontium sulfide powder and a small amount of CeF$_3$ (purity, 99.99%) at 1000°C for 50 min in N$_2$ + H$_2$S. The SrSe:Ce$^{3+}$ phosphor was prepared in the same manner by firing the mixture of the strontium selenide powder and CeF$_3$ at 1050°C for 50 min in N$_2$, together with a small amount of NaF as flux. In the preliminary experiments it was determined that added NaF is useful in improving the luminescent efficiency of the Ce$^{3+}$ centers and does not produce any additional emission and excitation bands in the spectral range where the measurements were made.

X-ray diffraction patterns for the furnished phosphors showed that they are well crystallized in the rock salt type structure ($a = 6.02\AA$ for SrS:Ce$^{3+}$ and 6.25\AA for SrSe:Ce$^{3+}$, Na$^+$) and that there are no detectable traces of carbonate, selenide, or oxide.

Photoluminescence measurements.—The experimental apparatus used to observe the PL and excitation spectra has been described in the previous paper (6). The digitalized data of the PL signals were stored automatically in a floppy disk through a personal computer with a GP-IB interface. The PL and excitation spectra were drawn on an X-Y plotter after the correction for the spectral sensitivity of the spectroscopic system.

Results and Discussion

Photoluminescence.—Figure 1 shows the PL spectra of the SrS:Ce$^{3+}$ and SrSe:Ce$^{3+}$ phosphors at 300 and 80 K. The emission bands I and II correspond to the transi-
tions from the $T_{2g}$ state to the $2F_{5/2}$ and $2F_{7/2}$ states, respectively. The saddle part between the two emission bands becomes markedly deeper at 80 K owing to the suppression of lattice vibrations in the initial state.

Figure 2 shows the vibrational structures of the emission and excitation bands of the SrS:Ce$^{3+}$ and SrSe:Ce$^{3+}$ phosphors at 6 K. The shape of the emission spectra (curve 1) is almost similar to that obtained at 80 K (Fig. 1), except that two phonon series (i, ii) appear on the emission band I and three phonon series (iii, iv, v) on the band II. On the excitation band (curve 2) one can also observe well-defined two-phonon series (vi, vii). The fact that the zero phonon line of the series (vii) on the excitation band (vi) suggests the excitation band corresponds to the $2F_{7/2} \rightarrow T_{2g}$ transition. The $2F_{5/2} \rightarrow 2E_{g}$ excitation band cannot be observed, being masked by the fundamental absorption. This makes the higher energy part of the excitation spectra almost similar to the diffused absorption spectra of the corresponding host powder crystal (6). It is cut off, therefore, from the figure.

Table I shows the frequencies, $\omega_{TO}$ and $\omega_{LO}$, of the TO and LO phonons of host crystal (7) and the localized phonon frequencies, $\omega_{a}$ and $\omega_{m}$, that is, the intervals of the phonon series observed on the excitation and emission bands, respectively [cf. Fig. 2], for some alkaline earth chalcogenide phosphors activated with Ce$^{3+}$ ions. One can see the trends $\omega_{a} < \omega_{m} < \omega_{0}$ for the sulfides and $\omega_{a} = \omega_{m} = \omega_{0}$ for the selenides. Further research will be needed in order to clarify the mechanism producing these trends.

Energy matrices.—Three energy matrices for the $\Gamma_{a}$, $\Gamma_{t}$, $\Gamma_{g}$ substrates resulting from the 4f configuration and two energy matrices for the $\Gamma_{a}$, $\Gamma_{t}$ substrates resulting from the 5d configuration are shown in the Appendix. The matrix elements of the former and the latter take the form of linear combinations in four energy parameters $A_{t}$, $\zeta_{t}$, $V_{t}^{(1)}$, $V_{t}^{(10)}$ and in three ones $A_{s}$, $\zeta_{s}$, 10 $D_{q}$, respectively. The notations $A_{t}$ and $A_{s}$ mean the energies of the 4f and 5d orbitals, respectively, while $\zeta_{t}$ and $\zeta_{s}$ denote the coupling constants of the spin-orbit interaction for both the orbits. The crystal parameter for the 5d orbit is denoted by 10 $D_{q}$, whereas those of the fourth and sixth orders for the 4f orbit by $V_{t}^{(1)}$ and $V_{t}^{(10)}$, respectively. As these matrices have a rank not higher than two, the secular equations referring to them can be solved algebraically. Owing to the smallness of their nondiagonal elements, each one of their diagonal elements may be considered as expressing approximately the energy of the corresponding state.

Analysis of spectra.—We determined the values of the energy parameters by same procedure as described in the previous papers (4, 5). At this time we only give an

| Table I. Frequencies (cm$^{-1}$) of TO and LO phonons and localized phonons |
|-----------------|-----------------|-----------------|-----------------|-----------------|
|                  | $\omega_{TO}$   | $\omega_{LO}$   | $\omega_{a}$    | $\omega_{m}$ |
| CaS:Ce$^{3+}$    | 229             | 342             | 278, 282        | (a) 294, 293   |
| SrS:Ce$^{3+}$    | 185             | 282             | 246, 250        | (b) 294, 294, 294 |
| CaSe:Ce$^{3+}$   | 168             | 220             | 168, 166        | (a) 168, 167   |
| SrSe:Ce$^{3+}$   | 141             | 201             | 144, 146        | (b) 159, 168, 168 |

The frequencies (a) and (b) correspond to the phonon series on the emission bands I and II, respectively.

The values of the energy parameters calculated are shown in Table II together with those of other alkaline earth chalcogenide phosphors activated with Ce\(^{3+}\) ions. The value of the parameter \(\zeta_t\) remains nearly unchanged for various host crystals owing to the electric screening, whereas the values of \(V_t^{(n)}\) and \(V_s^{(n)}\) decrease gradually as the ionic radius of host ingredients increases. It has also been found that the parameter \(\zeta_t\) for other trivalent rare earth ions is conspicuously independent of host ingredients (9).
