Abstract

HER2 is a member of the HER family proteins containing four receptor tyrosine kinases and plays an important role in the pathogenesis of certain human cancers. In non-small cell lung cancer (NSCLC), HER2 amplification or mutations have been reported. However, little is known about the benefit of HER2-targeted therapy for NSCLCs harboring HER2 alterations. In this study, we investigated the anti-tumor effect of afatinib, an irreversible EGFR/HER2 dual inhibitor, in lung cancers harboring HER2 oncogene alterations, including novel HER2 mutations in transmembrane domain, which we recently identified. Normal bronchial epithelial cells, BEAS-2B, ectopically overexpressing wild-type HER2 or mutants (A775insYVMA, G776VC, G776LC, P780insGSP, V659E, and G660D) showed constitutive autophosphorylation of HER2 and activation of downstream signaling. They were sensitive to afatinib, but insensitive to gefitinib. Furthermore, we examined the antitumor activity of afatinib and gefitinib in several NSCLC cell lines, and investigated the association between their genetic alterations and sensitivity to afatinib treatment. In HER2-altered NSCLC cells (H2170, Calu-3, and H1781), afatinib down-regulated the phosphorylation of HER2 and EGFR as well as their downstream signaling, and induced an antiproliferative effect through
G1 arrest and apoptotic cell death. In contrast, HER2- or EGFR-non-dependent NSCLC cells were insensitive to afatinib. In addition, these effects were confirmed in vivo by using a xenograft mouse model of HER2-altered lung cancer cells. Our results suggest that afatinib is a therapeutic option as a HER2-targeted therapy for NSCLC harboring HER2-amplification or mutations. (235 words)

**Key words:** non-small cell lung cancer, HER2, ERBB2, HER2-targeted therapy, afatinib

**Abbreviations:** HER2, human epidermal growth factor receptor 2; NSCLC, non-small cell lung cancer; EGFR, epidermal growth factor receptor; TKI, tyrosine kinase inhibitor; ALK, anaplastic lymphoma kinase
Introduction

Lung cancer remains the leading cause of cancer-related death worldwide.\(^{(1)}\) Recent developments in the genomic characterization of tumors have contributed to novel therapeutic approaches, and some molecular-targeted therapies based on the genetic profiles of tumors have improved patient survival. For example, epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs), such as gefitinib or erlotinib, have shown marked antitumor activity in non-small cell lung cancer (NSCLC) patients with an activating EGFR mutations, and crizotinib, an anaplastic lymphoma kinase (ALK) TKI, has shown similar promise for NSCLC patients with ALK gene rearrangements.\(^{(2, 3)}\) Furthermore, other oncogenic alterations, such as KRAS, NRAS, BRAF, MET, and FGFR, have been identified in some subsets of NSCLC.\(^{(4, 5)}\)

Human epidermal growth factor 2 (HER2, also known as ERBB2) is a member of the HER family containing four receptor tyrosine kinases. This receptor is frequently overexpressed in various human cancers, and many preclinical studies have shown that overexpression of HER2 or mutations of the HER2 kinase domain play an important role in oncogenic transformation and tumorigenesis.\(^{(6-9)}\) In NSCLC patients, HER2 overexpression and HER2...
amplification were reported in 11% to 32% and in 2% to 23%, respectively.\(^{(10-13)}\)

HER2 mutations were identified in approximately 2% to 4% of NSCLCs and were usually mutually exclusive with other driver mutations.\(^{(14, 15)}\) Shigematsu et al. reported that all HER2 mutations in tyrosine kinase domain were located in a same loop of exon 20, consisting of A775insYVMA (55%), G776VC (18%), P780insGSP (18%), and G776LC (9%).\(^{(15)}\) Recently, we have identified two novel mutations in the transmembrane domain of HER2 encoded by exon 17 (V659E and G660D) in lung adenocarcinomas. Our preliminary data suggested that these mutations might be oncogenic alterations of lung adenocarcinoma.\(^{(16)}\) However, little is known about the benefit of HER2-targeted therapy for NSCLCs harboring HER2 alterations.

Afatinib, also known as BIBW2992, is an irreversible inhibitor of EGFR and HER2, and has recently been approved for the treatment of EGFR-mutant NSCLCs in several countries. In two randomized phase III trials, afatinib showed significant benefit in progression-free survival compared with standard doublet chemotherapy in NSCLC patients with EGFR mutations.\(^{(17, 18)}\)

In this study, we investigated the efficacy of afatinib as a HER2-targeted therapy \textit{in vitro} in NSCLC cells harboring HER2 gene amplification or mutations,
including novel mutations in transmembrane domain, and confirmed these antitumor effects \textit{in vivo} via a xenograft mouse model of HER2-altered lung cancer cells.

\section*{Materials and Methods}

\subsection*{Cell lines and reagents}

Eight lung cancer cell lines (A549, Calu-3, HCC827, NCI-H1299, NCI-H1781, NCI-H1975, NCI-H1993, and NCI-H2170), two breast cancer cell lines (SK-BR-3 and BT-474), and one normal human bronchial epithelial cell line (BEAS-2B) were used in this study. These cell lines, except A549, SK-BR-3, BT-474 and BEAS-2B, were kindly provided by Dr. Adi F. Gazdar (The University of Texas Southwestern Medical Center at Dallas, Dallas, TX, USA), who established these lines with Dr. John D. Minna.\cite{19, 20} A549, SK-BR-3 and BT-474 were purchased from American Type Culture Collection (Manassas, VA). BEAS-2B was purchased from European Collection of Cell Cultures (Porton Down, UK). All lung cancer cells were cultured in RPMI 1640 media supplemented with 10\% fetal bovine serum (FBS) and the other cells were maintained in DMEM with 10\% FBS. They were grown in a humidified incubator with 5\% \text{CO}_2 at 37°C. Afatinib and
gefitinib were purchased from Sykkinase Pty Ltd. (San Diego, CA, USA) and InvivoGen (San Diego, CA), respectively.

**Plasmid constructs and transfection**

Human cDNAs encoding full-length HER2 (wild-type and its variants A775insYVMA, G776VC, G776LC, P780insGSP, V659E, and G660D) were inserted into the pIDT-SMART (C-TSC) vector, pCMViR-TSC \(^{(21)}\), respectively. Transient transfection of the BEAS-2B cells with the mammalian expression vectors was performed using Lipofectamine 3000 (Life Technologies, Carlsbad, CA) according to the manufacturer’s protocol.

**Three-dimensional structure analysis**

A three-dimensional structure model of HER2-afatinib was made by copying afatinib coordinates to the substrate binding pocket of a HER2 kinase domain structure (PDB ID: 3RCD) from a superimposed EGFR-afatinib complex structure (PDB ID: 4G5J). The HER2 mutation sites of exon 20 reported in previous papers were mapped on the modeled complex structure. The figure was prepared using PyMOL (Schrödinger, New York, NY).

Secondary structure assignment for the HER2 kinase domain structure was performed with STRIDE to determine the residue numbers of beginning and
end of the αC-β4 loop of HER2 kinase domain.\textsuperscript{(22)}

**Western blot analysis**

The total cell lysate was extracted with lysis buffer, a mixture of RIPA buffer, phosphatase inhibitor cocktails 2 and 3 (Sigma-Aldrich, St. Louis, MO), and Complete Mini (Roche, Basel, Switzerland). Western blot analysis was performed by conventional methods using the following primary antibodies: anti-EGFR, phospho-EGFR (Tyr1068), HER2, phospho-HER2 (Tyr1221/1222), Akt, phospho-Akt (Ser473), p44/p42 mitogen-activated protein kinase (MAPK), phospho-p44/p42 MAPK, cleaved PARP (Asp214) (Cell Signaling Technology, Danvers, MA), and β-actin (used as loading control, Merck Millipore, Billerica, MA). The secondary antibody was horseradish-peroxidase (HRP)-conjugated anti-mouse or anti-rabbit IgG (Santa Cruz Biotechnology, Dallas, TX). To detect specific signals, the membranes were examined using the ECL Prime Western Blotting Detection System (GE Healthcare, Amersham, UK) and LAS-3000 (Fujifilm, Tokyo, Japan).

**DNA extraction**

Genomic DNA was obtained from the cell lines with a DNeasy Blood and Tissue Kit (Qiagen, Valencia, CA) according to the manufacturer's instructions.
Copy number analysis by real-time PCR

Copy number gains of \textit{EGFR} and \textit{HER2} were measured by real-time quantitative PCR (qPCR) with the SYBR Green Method, using Power SYBR Green PCR Master Mix (Life Technologies), as previously reported. \cite{23} In brief, \textit{LINE-1} was used as a reference gene for each copy number analysis. The dosage of each target and reference gene was calculated by the standard curve method. Relative copy number of each sample was determined by comparing the ratio of the target gene to \textit{LINE-1} in each sample with the ratio of these genes in standard genomic DNA (Merck KGaA, Darmstadt, Germany).

Cell growth inhibition assay

Cells were cultured with or without drugs for 72 hours and the sensitivities to the drugs were determined using a modified MTS assay with CellTiter 96 Aqueous One Solution Reagent (Promega, Fitchburg, WI), as previously described. \cite{24} The antiproliferative activities of each drug are shown as IC$_{50}$, which is the concentration of the drug required to inhibit cell proliferation by 50%.

Cell cycle analysis

The effects of afatinib on the cell cycle distribution were assessed using
a propidium iodide staining-based assay with the CycleTEST PLUS DNA Reagent Kit and FACSCaliber (Becton Dickinson, Franklin Lakes, NJ). Untreated cells and cells treated with 0.1 μM afatinib for 24 or 48 hours were subjected to cell cycle analysis. Doublets, cell debris, and fixation artifacts were gated out, and cell cycle analysis was performed with CellQuest, version 3.1.

**Xenograft model**

Six-week-old nonobese diabetic/severe combined immunodeficient (NOD/SCID) female mice were purchased from Charles River Laboratories (Yokohama, Japan). All mice were provided with sterilized food and water, and housed in a barrier facility under a 12-hour light/12-hour dark cycle. Each cell line (5 × 10^6) was suspended with 200 μl RPMI 1640 media with Matrigel Basement Membrane Matrix (Corning, Corning, NY) and subcutaneously injected into the backs of the mice. The tumor volume was calculated using the empirical formula $V = \frac{1}{2} \times [(\text{the shortest diameter})^2 \times (\text{the longest diameter})]$. When the tumors exceeded approximately 50 mm³, mice were randomly allocated to two groups that received either vehicle or 20 mg/kg afatinib. Afatinib was prepared in 0.5 w/v (%) methyl cellulose. Vehicles and afatinib were administered orally as a suspension by gavage once daily, six days per week. Tumor volume was
measured three times a week with calipers. After 4 weeks of treatment, the mice were sacrificed and the tumors were harvested and photographed.

**Statistical analysis**

Statistical analysis was performed with GraphPad Prism, version 6.0.3, J (GraphPad Software, San Diego, CA). Group differences were compared using one-way ANOVA followed by Dunnett’s test or two-way ANOVA for repeated measurements. $P < 0.05$ was considered statistically significant.

**Results**

**HER2 alteration activates HER2 signaling, which is inhibited by afatinib**

To examine the effect of HER2 alterations on signal transduction pathways, normal bronchial epithelial cells (BEAS-2B) were transiently transfected with wild-type or six mutant HER2-containing vectors, consisting of four kinase domain mutations (A775insYVMA, G776VC, G776LC, and P780insGSP) and two transmembrane domain mutations (V659E and G660D), which were reported in NSCLCs. $^{15, 16}$ Cells expressing wild-type and all six HER2 mutants showed strong constitutive autophosphorylation of HER2 in the absence of serum, and stronger phosphorylation of EGFR, which is assumed to
be one of HER2 dimerization partners, and AKT compared with the vector control. Furthermore, all cells expressing HER2-mutants showed increased phosphorylation of HER2, EGFR, and AKT compared with those expressing wild-type (Fig. 1A).

Next, we assessed the affinity changes of afatinib to HER2 kinase domain caused by major HER2 mutations in exon 20. We modeled the three-dimensional structure of HER2-afatinib complex and marked the location of major HER2 mutations, which are reported in the previous paper (15) (Fig.1B). Mutations of exon 20 were concentrated in the exposed area on the protein surface (from A775 to P780) of the αC-β4 loop (from M774 to R784) of the HER2 kinase domain, and this area was located on the back side of the ATP-binding pocket as shown in its modeled complex structure. This structural feature suggests that the major HER2 mutations in exon 20 could not directly inhibit the binding of ATP and afatinib to the HER2 kinase domain.

We then examined the sensitivity of BEAS-2B cells ectopically expressing wild-type or mutant HER2 to the EGFR-TKI (gefitinib) and EGFR/HER2-TKI (afatinib). Forty-eight hours after transfection, cells were treated with or without gefitinib or afatinib for six hours. We then analyzed the HER2 signaling pathway
via western blotting. Although gefitinib showed little effect on the phosphorylation of HER2 and EGFR, treatment with afatinib inhibited phosphorylation of HER2, EGFR, and AKT (Fig. 1C). These results indicate that afatinib was more effective than gefitinib in inhibiting HER2-driven signals.

**Afatinib inhibits growth of both HER2-amplified and HER2-mutant lung cancer cells**

We examined the antitumor activity of afatinib and gefitinib in several NSCLC cell lines, and investigated the association between their genetic alterations and sensitivity to afatinib treatment (Table 1 and Fig. 2A). The cell lines of this panel were selected on the basis of previously published genotyping reports\(^\text{19, 25}\) and consisted of 2 HER2-amplified (NCI-H2170 and Calu-3), 1 HER2-mutant (NCI-H1781), 2 EGFR-mutant (NCI-H1975 and HCC827), 1 KRAS-mutant (A549), 1 NRAS-mutant (NCI-H1299), and 1 MET-amplified (NCI-H1993) NSCLC cell lines; two HER2-amplified breast cancer cell lines (SK-BR-3 and BT-474) were also analyzed. We determined the copy number gains of EGFR and HER2 using real-time PCR, and sensitivity was assessed, with the IC\(_{50}\) values for each cell line calculated using an MTS assay. Two NSCLC cell lines,
H2170 and Calu-3, and two breast cancer cell lines, SK-BR-3 and BT-474, showed high HER2-amplification, with copy number values of 94.6, 110.9, 23.0, and 32.0, respectively. In contrast, copy number values of HER2 in H1781 cells (HER2-mutant cells) or the other cell lines in this panel did not exceed approximately 3. Next, for drug sensitivity, the proliferation of two HER2-amplified lung cancer cell lines, H2170 and Calu-3, was inhibited by afatinib, with IC\(_{50}\) values of 0.140 and 0.086 μM, respectively. Afatinib also exhibited strong antiproliferative effects on H1781 cells, with an IC\(_{50}\) of 0.039 μM. Regarding the sensitivity to gefitinib among HER2-altered cells, H2170 and H1781 cells, were resistant to gefitinib (IC\(_{50}\) > 3 μM). On the other hand, Calu-3 cells were partially sensitive to gefitinib, with an IC\(_{50}\) of 0.471 μM, which was consistent with a previous report.\(^{(26)}\) Furthermore, HCC827 cells (EGFR-mutant) were sensitive to afatinib with IC\(_{50}\) values of 0.001, and H1975 cells (EGFR-L858R/T790M mutant) were moderately resistant to afatinib with IC\(_{50}\) values of 0.713 μM. HER2- or EGFR-non-dependent NSCLC cells A549 (KRAS-mutant cells), H1299 (NRAS-mutant cells), and H1993 (MET-amplified cells), were insensitive (IC\(_{50}\) > 2 μM). In addition, afatinib showed antiproliferative effects on HER2-amplified breast cancer cell lines (SK-BR-3 and BT-474 cells), with an IC\(_{50}\) of 0.002 μM for each
Next, we assessed the effect of afatinib on signal transduction pathways in HER2-amplified or HER2-mutant lung cancer cells. After six hours of treatment with afatinib, cells were lysed followed by western blot analysis. As shown in Fig. 2B, afatinib potently inhibited phosphorylation of both HER2 and EGFR at a concentration of 0.1 μM, and the downstream signals, phosphorylation of AKT and MAPK, were also inhibited in both HER2-amplified and HER2-mutant lung cancer cells. Taken together, these results suggest that afatinib showed strong antitumor activity in both HER2-amplified and HER2-mutant lung cancer cells in vitro.

Afatinib induces cell-cycle arrest and apoptosis in HER2-dependent cells

To assess the mechanism of growth inhibition, we then examined the effect of afatinib on cell cycle and apoptosis in HER2-amplified (H2170 and Calu-3 cells), HER2-mutant (H1781 cells), and HER2- or EGFR-non-dependent lung cancer cells (A549 cells). Cells were treated with 0.1 μM afatinib for 24 or 48 hours, and analyzed by flow cytometry. To analyze cell cycle distribution, the sub-G1 fraction was excluded and the percentages of each phase were measured
(Fig. 3A). Treatment with afatinib caused an increase in the number of H2170, Calu-3, and H1781 cells occupying the G1 phase relative to untreated cells, whereas G1 arrest was not detected in A549 cells. Next, we investigated the ability of afatinib to induce apoptosis. Cell apoptosis was analyzed with cleaved PARP antibody, as an apoptosis marker, by western blotting. Afatinib (0.1 μM) induced apoptosis in a time-dependent manner in H2170, Calu-3, and H1781 cells; however, A549 cells did not express cleaved PARP with the treatment (Fig. 3B). These results showed that afatinib induced antiproliferative effects through G1 arrest and apoptotic cell death in HER2-altered cells (H2170, Calu-3, and H1781 cells), whereas HER2- or EGFR-non-dependent NSCLC cells were insensitive to afatinib.

**Antitumor effect of afatinib on a xenograft mouse model of HER2-altered cells**

On the basis of our *in vitro* data, we investigated the antitumor effect of afatinib in a xenograft mouse model of HER2-driven lung cancer. H2170 cells (*HER2*-amplified cells) and H1781 cells (*HER2*-mutant cells) were used in this experiment. The dose of afatinib was chosen on the basis of previous reports. (9,
One week after transplantation, when tumors exceeded approximately 50 mm³, we started to orally administer vehicle alone or afatinib at 20 mg/kg for six days per week. As shown in Fig. 4A, B, C, and D, afatinib treatment significantly inhibited the tumor growth of both H2170 and H1781 xenografts compared with the vehicle control ($P < 0.0001$ by repeated measurements of ANOVA).

**Discussion**

HER2 is frequently overexpressed in various human cancers, and targeted therapies for HER2-positive tumors have been proven clinically effective in breast and gastric cancers.\(^{28, 29}\) However, it is still unclear whether HER2-targeted therapy shows clinical benefit in NSCLC patients with HER2 aberrations. Previous clinical trials failed to show a clinical benefit with trastuzumab monotherapy or an additional effect of trastuzumab to conventional first-line chemotherapy in HER2-positive NSCLC patients by immunohistochemistry (IHC) analysis.\(^{30-32}\) On the other hand, a subgroup of patients with high HER2 expression (IHC 3+), HER2 gene amplification, or HER2 mutations were observed to have a good response to HER2-targeted treatment.\(^{30, 33, 34}\) Patient selection based on molecular profiles of tumor cells is important for achieving the
maximum benefit of the targeted therapy, because preferable responses can be
diluted easily without optimal patient selection. Therefore, to determine the
optimal patient selection for HER2-driven NSCLCs, further clinical and preclinical
investigations are required.

In previous preclinical studies, Perera et al. reported the efficacy of
afatinib and the combination of afatinib with mTOR inhibitor rapamycin in HER2-
mutant A775insYVMA transgenic mice or H1781 xenografts. As for other
EGFR/HER2-TKIs, neratinib (HKI-272) or dacomitinib (PF00299804) showed
efficacy in lung cancer cells with HER2 amplification or mutation in vitro. In
this study, we showed that afatinib efficiently inhibited growth of both HER2-
amplified and HER2-mutant lung cancer cells as well as that of EGFR-mutant
lung cancer cells at clinically achievable concentration via G1 arrest and
apoptotic cell death. In addition, we showed afatinib inhibited HER2
phosphorylation in HER2-mutant cells in the transmembrane domain. These facts
were confirmed in BEAS-2B cells with various HER2 mutants transfection. While
the rate of HER2 mutations in the transmembrane domain is rare, afatinib may
be a therapeutic option in patients with this alteration.

Regarding the HER2 mutations in lung cancer, reported mutations are
concentrated in exon 20 and the majority of these mutations are A775insYVMA, G776VC, G776LC, and P780insGSP except one mutation L755S in exon 19\(^ {15}\) and two transmembrane domain mutations V659E and G660D in exon 17.\(^ {16}\)

According to COSMIC database (http://cancer.sanger.ac.uk/cosmic), A775insYVMA, G776VC, G776LC, and P780insGSP mutations account for 74% of all HER2 mutations in lung cancers. In addition, mutations in the αC-β4 loop (M774-R784) of the HER2 kinase domain account for 81% of HER2 mutations at the time of our survey on October 12, 2015. As mentioned, the three-dimensional structure of the modeled HER2-afatinib complex shows that the major mutations of HER2 are concentrated in the exposed area (A775-P780) of the αC-β4 loop, which is located on the back side of the ATP-binding pocket. Thus, these mutations are considered not to directly inhibit the binding of afatinib to HER2 kinase domain. These facts with our experimental results support that afatinib is effective for majority of HER2 mutations.

Though EGFR-mutant NSCLCs initially respond to the antitumor effects of EGFR-TKIs, most of these tumors eventually acquire resistance to the treatment. Several mechanisms of resistance have been reported, and secondary T790M mutation in exon 20 of EGFR is the most common one.\(^ {40, 41}\)
In addition, Takezawa et al. recently reported \textit{HER2} amplification as a novel mechanism of acquired resistance to reversible EGFR-TKIs in patients with NSCLCs harboring \textit{EGFR}-mutations.\textsuperscript{(42)} Considering the findings we obtained, afatinib may be useful for overcoming reversible EGFR-TKI resistance acquired via \textit{HER2} amplification.

In conclusion, we demonstrated the antitumor effect of afatinib in lung cancers harboring \textit{HER2} alterations. Our results suggest that afatinib is a therapeutic option as a \textit{HER2}-targeted therapy for NSCLC harboring \textit{HER2}-amplification or mutations.
